## Analysis of Singlestep GTa-BLUP for Nordic Holstein cattle

Trine Andersen (SEGES/NAV), Ulrik Nielsen (SEGES/NAV)

Based on Nordic Holstein cattle several analyses are made to examine how well singlestep GTa-BLUP perform.

### Analyses:

1. Most extreme cases of difference between single-step GEBV and EBV .....	2
2. Comparison of GTa-BLUP and twostep .....	3
3. Comparison of EBV's from two different models- one model where herd year is a random effect (official model) or another model without fixed 5 year period but fixed herd year. ....	16
4. Comparison of EBV and GEBV from GTa-BLUP for genotyped and non-genotyped cows with and without own records. ....	19
5. Genetic trend for equal groups of cows .....	22
6. Comparison of parent average and GTa-BLUP .....	24
7. Comparison of PA GEBV and own GEBV for cows with records in full but not in reduc .....	36
8. Comparison of status1 bulls divided into four groups based on number of daughters with records in full data.....	37
9. Regression of GEBV_full on GEBV_reduc and Trad_full for status1 bulls divided into daughter groups	
40	
10. Comparison of own GEBV and parent average GEBV where cows are divided into four groups by PA GEBV. ....	40
11. GTa-reduc2 for 2017, 2018, 2019 and 2020 for bulls .....	43
12. GTa-reduc2 for 2017, 2018, 2019 and 2020 for cows.....	46
13. Interbull validation for GTa (and two-step) for udder depth.....	50
14. Legarra Reverter regression for GTa (and two-step) for udder depth.....	51
15. Interbull validation for status1 bulls sub-grouped by number of daughters .....	51
16. Legarra Reverter regression for status1 bulls sub-grouped by number of daughters.....	52

Singlestep is run with a GTa-BLUP where foreign information is included. There are three models:

- Full model with all information
- Reduc: Daughters after Viking bulls (Status 1) born after 2011 not included with own record
- Reduc2: Females calved after 2016 own record removed.

# 1. Most extreme cases of difference between single-step GEBV and EBV

For non-genotyped cows with own record born after 2009 the difference between single-step and EBV is calculated and the most extreme cases are examined.

## Most extreme cases of difference for Chest width:

As shown in those four tables there are some cows (without genotype, with own records) where the difference between singlestep GEBV and EBV are either strongly positive or strongly negative. When looking into some of the cases it turns out that those cows have close relatives with a genotype and with high difference.

In a single-step this can affect both if it is a daughter or if it is the mother – thus both directions.

Furthermore, there is a correlation between some traits, and therefore being highly negative for chest width also shows highly negative diff for "body depth" and "Rear legs, back rear view" (as an example).

## **2. Comparison of GTa-BLUP and twostep**

Singlestep GEBV's are compared with GEBV's from a twostep model.

The pedigree is the same in all models.

Bulls are divided in four status groups

- status1 are Viking bulls
- status2 are international bulls
- status3 are bulls, which are tested but not selected
- status 4 has unknown status.

Results includes mean GEBV, STD of mean GEBV and correlations, and all results are shown both as table and as graph and for four groups of cattle.

## Selected bulls (status1)

There is a tendency for bull (status1) that mean GEBV for twostep is lower than for singlestep for chest width and for udder depth. This is however not the case for udder depth in the period 2005-2012, where mean GEBV for twostep is higher than singlestep.

Table1.1: Chest Width: Mean GEBV for bulls Status1

b_year	N	Two	full	reduc	reduc2
2005	334	102.6	102.2	102.1	102.1
2006	383	100.9	100.7	100.7	100.6
2007	334	101.6	101.6	101.6	101.5
2008	293	100.5	100.5	100.5	100.4
2009	269	99.4	99.6	99.7	99.8
2010	226	99.6	100.2	100.6	101.0
2011	167	100.5	100.9	101.3	102.2
2012	172	100.7	101.2	101.9	102.7
2013	120	100.7	101.2	101.7	102.2

2015	80	98.8	98.9	98.7	100.3
2016	66	98.4	98.6	98.9	99.1
2017	65	99.1	99.5	98.2	99.4
2018	89	98.7	99.2	98.2	99.3
2019	42	95.5	95.9	94.9	96.2

Table1.2: Udder Depth: Mean GEBV for bulls Status1

b_year	N	Two	full	reduc	reduc2
2005	334	87.5	86.5	86.6	86.6
2006	383	89.9	89.0	89.0	89.1
2007	334	91.7	91.0	91.0	91.0
2008	293	94.5	93.6	93.6	93.7
2009	269	95.3	94.5	94.7	94.6
2010	226	98.9	98.5	98.6	98.3
2011	167	99.3	98.9	98.6	98.1
2012	172	101.1	100.8	100.9	100.8
2013	120	105.6	106.3	106.0	106.1
2014	104	105.0	107.1	107.6	108.3
2015	80	109.5	112.6	113.5	113.6
2016	66	111.3	114.1	114.7	115.0
2017	65	112.3	115.6	115.9	116.3
2018	89	113.6	116.1	116.5	116.2
2019	42	114.0	117.1	116.8	117.0

There is a tendency that twostep is having lower STD of mean GEBV than singlestep. However, there are also exceptions of this tendency.

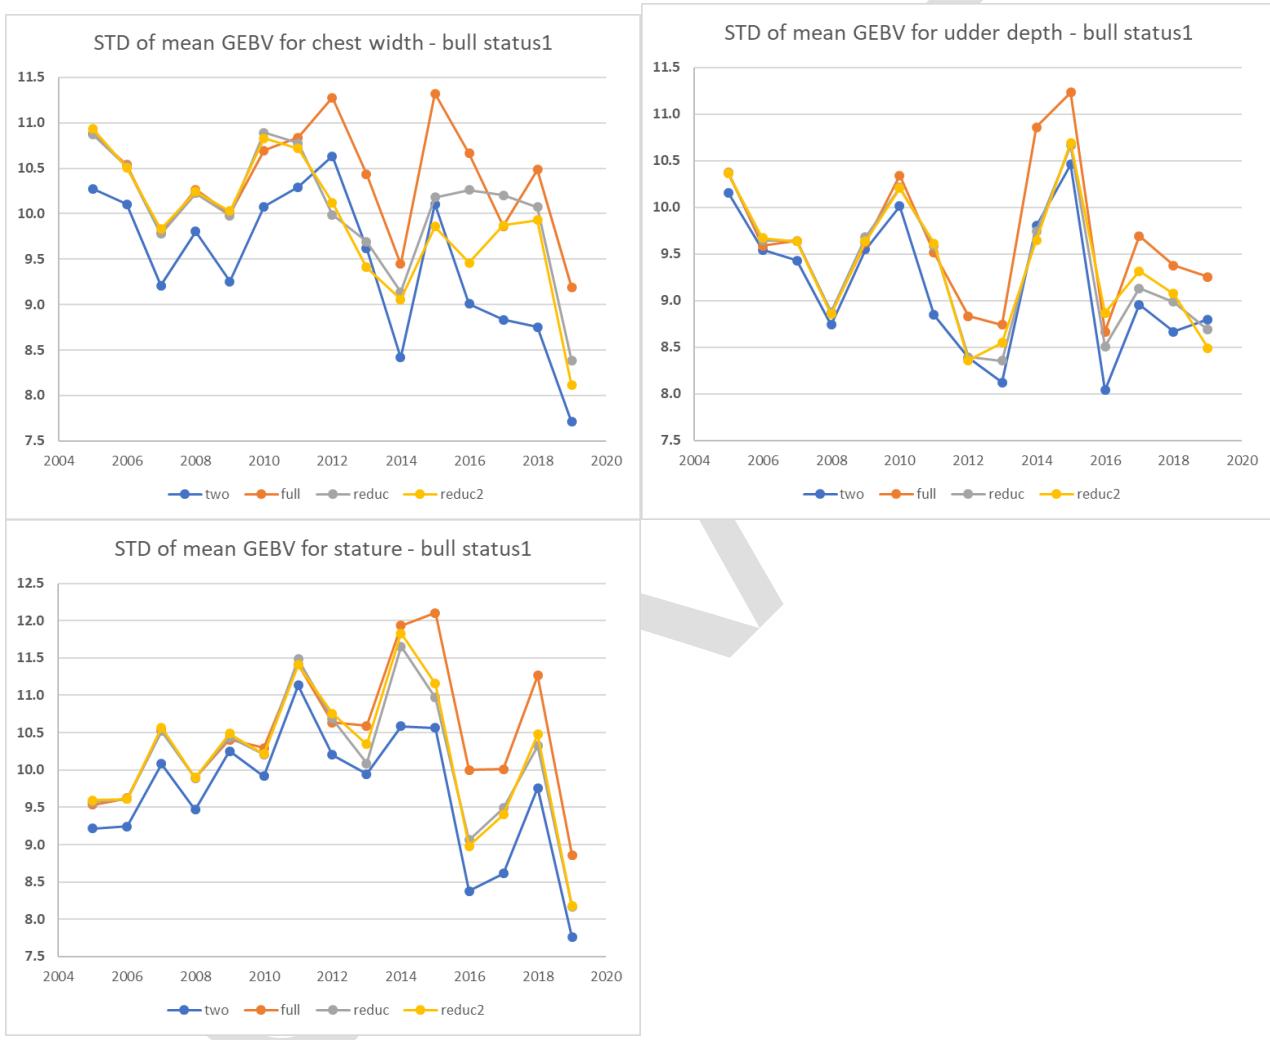

Table1.3: Chest Width: STD for Mean GEBV for bulls Status1

b_year	N	Two	full	reduc	reduc2
2005	334	10.3	10.9	10.9	10.9

2019	42	7.7	9.2	8.4	8.1	8.8	9.3	8.7	8.5	8.5

The correlation between twostep and singlestep full model is stable and high for the period 2005 to 2020 for both traits, whereas the correlation for twostep/reduc and twostep/reduc2 is high until 2011 and then it decreases.

Table1.5: Chest Width: Corr between Twostep and Singlestep (full/reduc/reduc2) for bulls Status1

2018	89	0.981	0.945	0.947
2019	42	0.984	0.928	0.914

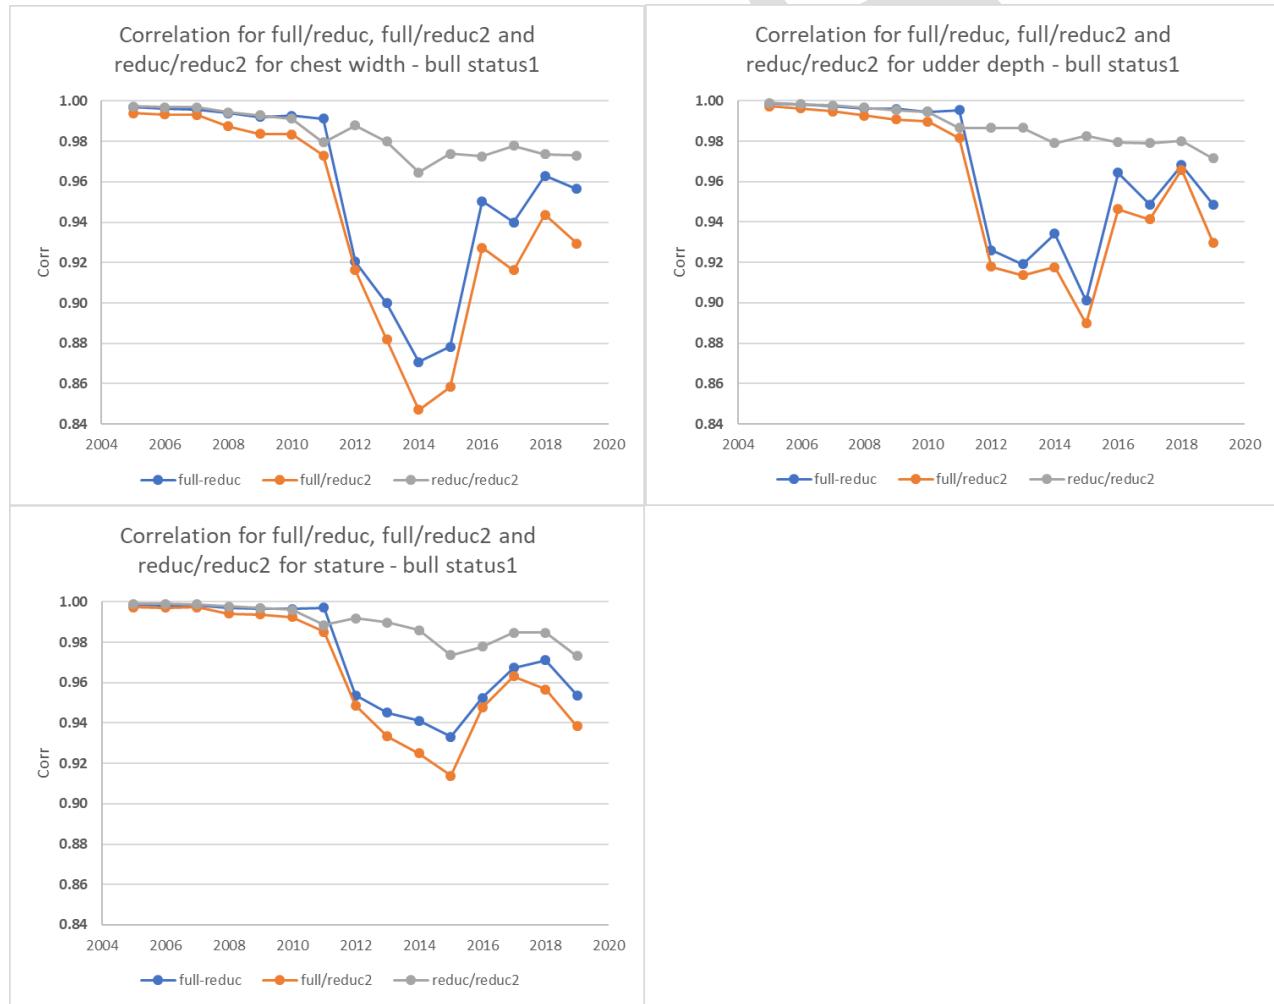

Correlations of mean GEBV between the three singlestep models show similarly high values until 2011. Then the correlation between full/reduc and between full/reduc2 decreases.

Table1.7: Chest Width: Corr between Singlestep (full/reduc og full/reduc2 and reduc/reduc2) for bulls Status1

b_year	N	full-reduc	full/reduc2	reduc/reduc2

## Bulls Status134 (thus excl. Status2)

Mean GEBV for twostep is slightly lower than singlestep for chest width in period 2008-2020 and for udder depth in period 2013-2020. For chest width the reduc2 is having the highest mean GEBV.

Table2.1: Chest Width: Mean GEBV for bulls Status134

Correlation for twostep to full, reduc and reduc2 for chest width - bull status134

Correlation for twostep to full, reduc and reduc2 for udder depth - bull status134

The highest correlations are seen between reduc/reduc2, while full/reduc2 is showing the lowest correlations. Generally, there is a decreasing correlation by year.

## Genotyped females

The mean GEBV's for twostep are comparable with singlestep (full/reduc/reduc2) for both chest width and udder depth. However, there is a tendency that singlestep is having higher means than twostep. Full model singlestep are close to twostep but reduc and especially reduc2 are higher than twostep. For 2005-2012 for udder depth the mean GEBV's of twostep is actually higher than singlestep.

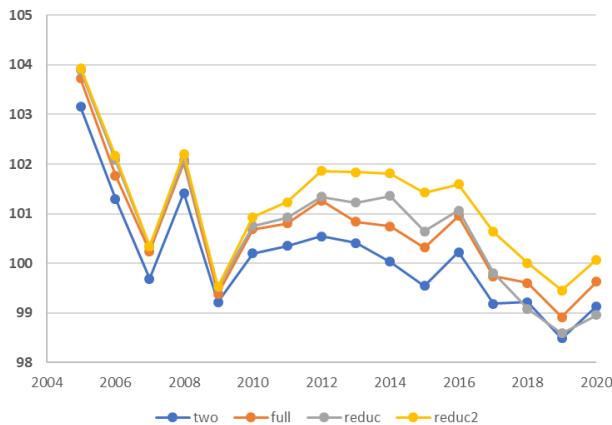

Table3.1: Chest Width: Mean GEBV for females

Looking at the correlation between the three singlestep models, the correlations for especially full/reduc and reduc/reduc2 are high until 2013. In the period 2015-2017 the correlations decrease, and full/reduc2 is decreasing the most while reduc/reduc2 is showing minor decrease.

Correlation for full/reduc, full/reduc2 and reduc/reduc2 for chest width

Correlation for full/reduc, full/reduc2 and reduc/reduc2 for udder depth

### 3. Comparison of EBV's from two different models- one model where herd year is a random effect (official model) or another model without fixed 5 year period but fixed herd year.

Nordic Holstein cows are divided into four groups:

- genotyped and with own record
- non-genotyped with own record
- genotyped without own record
- non-genotyped without own record

Results are showing means of EBV's from full, reduc and reduc2 models with herd year as random effect or with herd year as fixed effect but without fixed 5 year period. Only results for udder depth are shown and only if mean EBV is based on minimum 10 individuals.

Table 6.1 Udder depth: Mean EBV for genotyped cows with own record. Herd year effect as random (r), or fixed (f).

2020									

Overall there is a similar trend for EBVs no matter if herd year is included in the model as random or fixed effect.

EBV's for full models are having higher means than EBV's for reduc and reduc2 models especially in the later years.

#### 4. Comparison of EBV and GEBV from GTa-BLUP for genotyped and non-genotyped cows with and without own records.

Nordic Holstein cows are divided into four groups:

- genotyped and with own record
- non-genotyped with own record
- genotyped without own record
- non-genotyped without own record

Results are showing means of EBV's from full, reduc and reduc2 models and means of GEBV from GTa-full, GTa-reduc and GTa-reduc2. Only results where means are based on minimum 10 individuals are shown.

Results are shown for udder depth.

Here groups are not at equal size over full and reduc and reduc2.

Table 5.1 Udder depth: number of records and Mean EBV and GEBV for genotyped cows with own record.

2019									
2020									

Until 2013 there is a high similarity of mean EBV's and mean GEBV's from GTa no matter the group of cows for both full, reduc and reduc2 models. After 2013 GEBV from GTa is higher than EBV's and the difference is bigger for reduc and reduc2 than for full models. The biggest difference between EBV and GEBV is seen for genotyped cows without own record in the latest years.

From 2005 until 2013 the mean breeding value is higher for genotyped cows with own records than for the other three groups of cows.

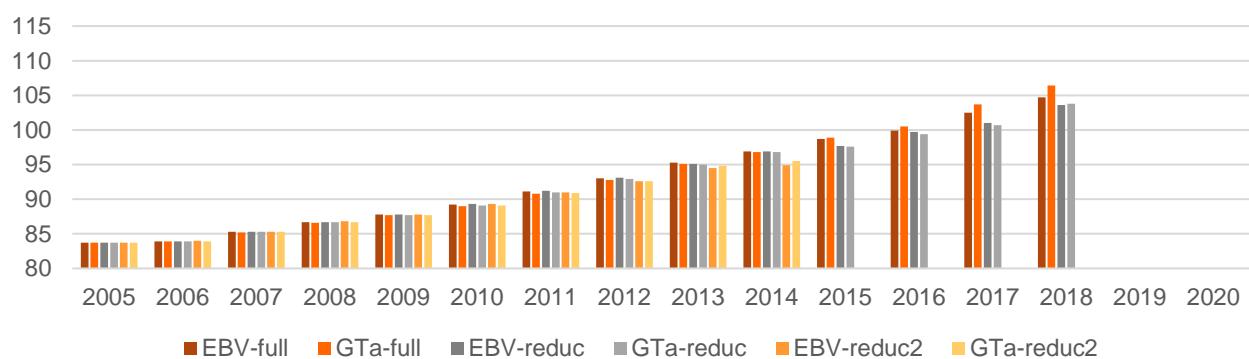

### Mean EBV's and GTa for genotyped cows with own records

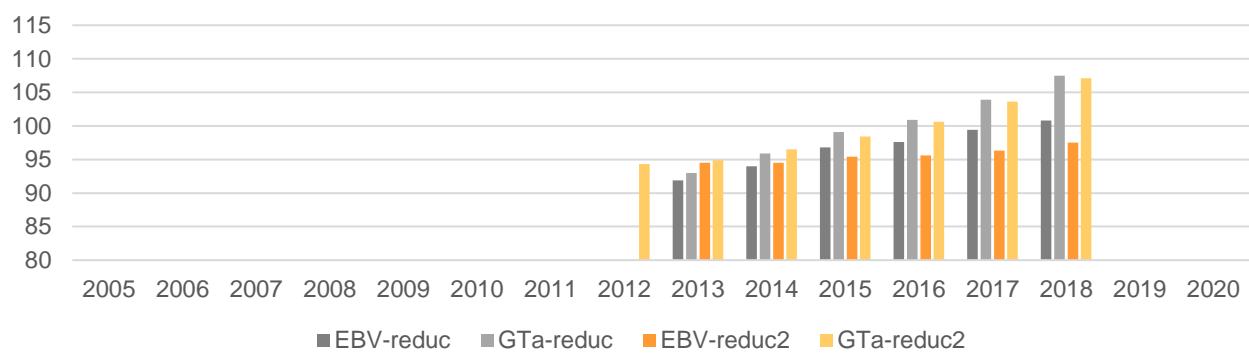

### Mean EBV's and GTa for genotyped cows without own records

### Mean EBV's and GTa for non-genotyped cows with own records

### Mean EBV's and GTa for non- genotyped cows without own records

## 5. Genetic trend for equal groups of cows

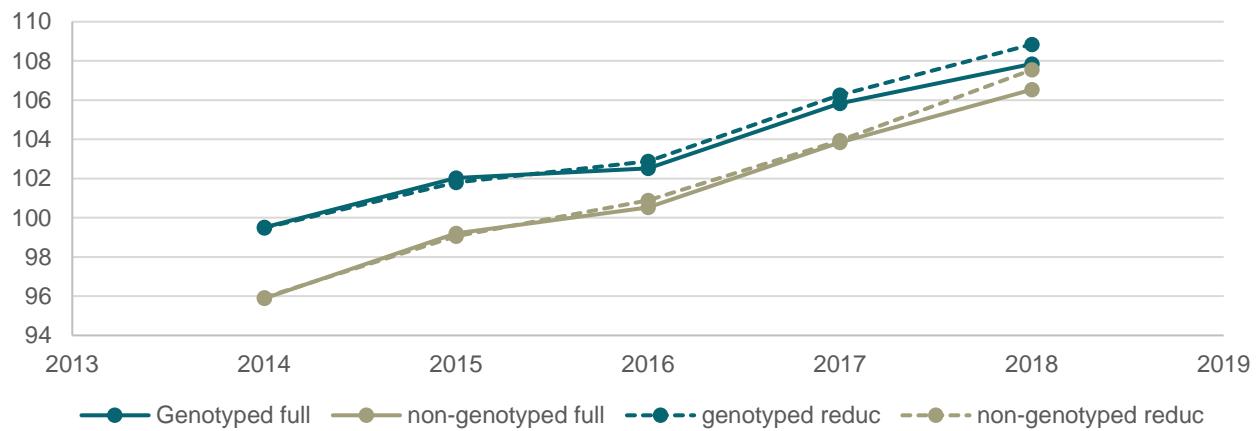

Here only cows which has records for full GTa but not for reduc GTa are included in the analysis. Those cows are divided into genotyped and non-genotyped cows.

Number of cows in each group

	Genotyped full	non-genotyped full	genotyped reduc	non-genotyped reduc
2013		67		67
2014	1590	18558	1590	18558
2015	6114	51595	6114	51595
2016	10575	58543	10575	58543
2017	11978	39993	11978	39993
2018	611	1322	611	1322

Genotyped cows are having higher means than non-genotyped cows. GTa-full and GTa-reduc is having high similarity. For non-genotyped cows the SD of mean GEBV is higher for full than reduced data. This fits well with the expectation that when more data is available (in full) then the accuracy increases and then the SD of mean GEBV increases. However, this tendency is not clear for genotyped cows, where the SD of mean GEBV is at similar level for full and reduc. This is a concern for singlestep.

cows with record in full data but without record in reduc data

Stature: SD of mean GEBV for GTa.  
cows with record in full data but without record in reduc data

## 6. Comparison of parent average and GTa-BLUP

For each individual the parent average of GTa-full GEBV is calculated based on the GTa-full for the dam and the sire. Only individuals where both parents have a GTa-full value is included.

For bulls with status1, it is examined if the GTa-full GEBV for the individual differs from the parent average GTa-full GEBV. For cows, first it is shown mean and SD of mean for all cows. Second, it is shown mean and SD of mean for genotyped and non-genotyped (with and without own records) cows which parents are genotyped.

### Bulls

For bulls the GTa-full own GEBV is close to the GTa-full parent average GEBV for both chest width and udder depth. There is though a tendency that own GEBV is slightly higher than PA GEBV for udder depth for the later years.

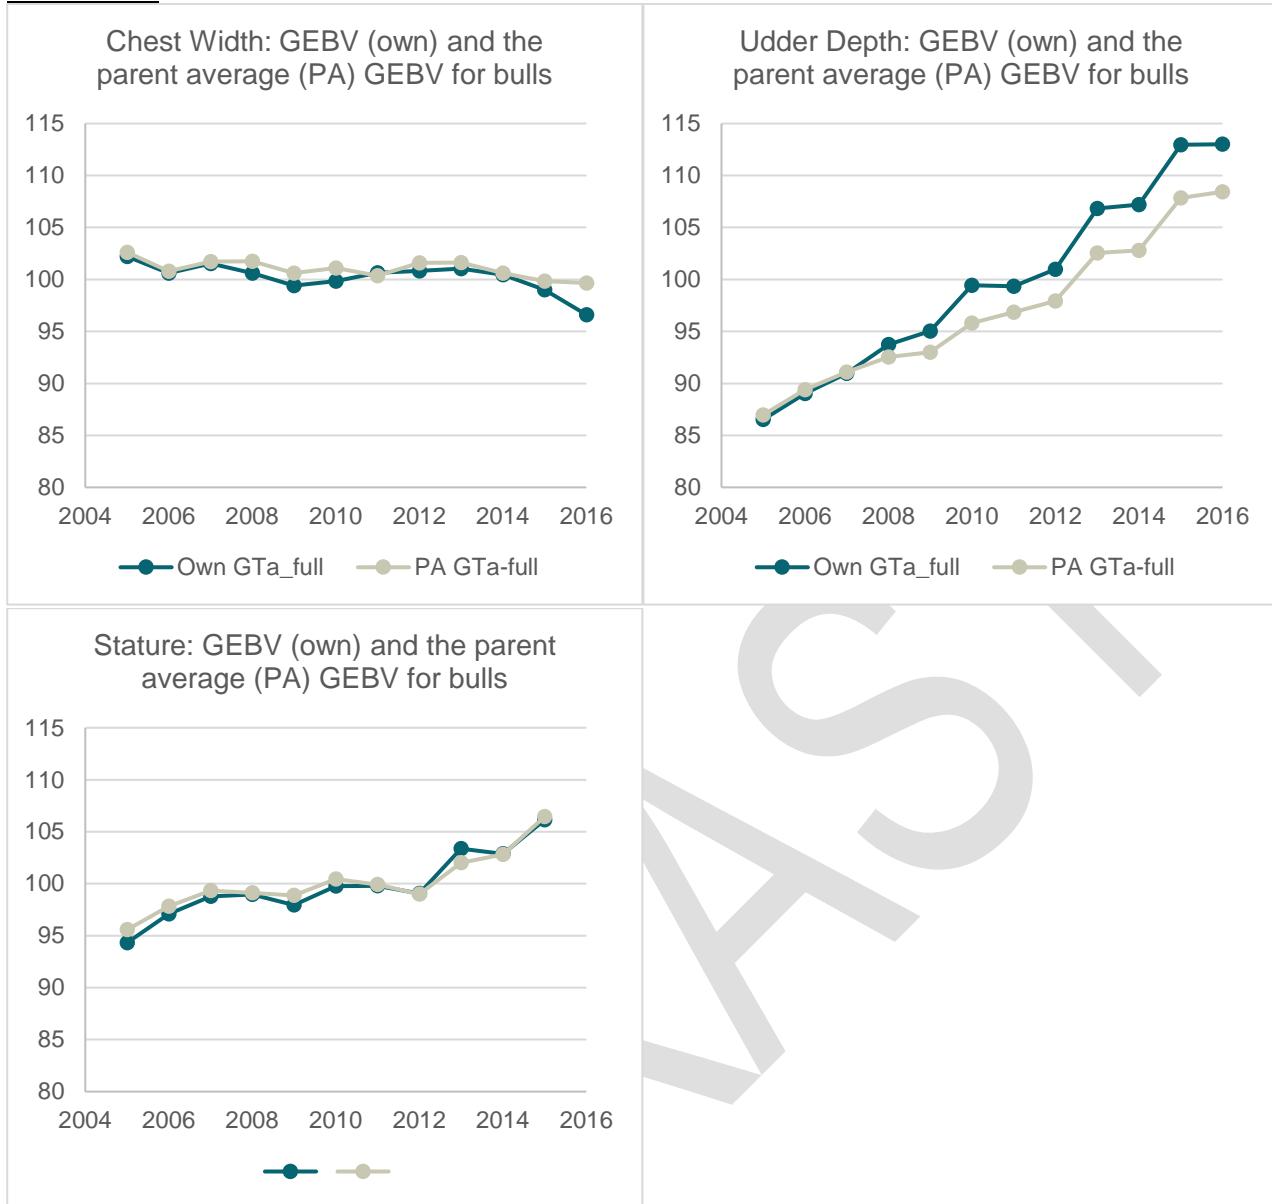

Table 7.1 Chest Width: mean GEBV (own solution) and the parent average (PA) GEBV for bulls status1.

b_year	N	Own GTa_full	PA GTa-full
2005	333	102.2	102.6
2006	376	100.6	100.8
2007	298	101.5	101.7
2008	246	100.6	101.8
2009	204	99.4	100.6
2010	173	99.8	101.1
2011	135	100.6	100.4

2015	71	112.9	107.8
2016	13	113.0	108.4

## Bull status1

The standard deviation (SD) of mean GEBV for own GTa-full and parent average GTa-full is not equal, as it is shown that SD for own GTa-full is higher than SD for PA GTa-full.

Table 7.3 Chest Width: SD of mean GEBV (own solution) and the parent average (PA) GEBV for bulls status1.

b_year	N	Own GTa_full	PA GTa-full

### Cows with genotyped parents

Results for cows, which parents are genotyped. The cows are divided into four groups

- genotyped and with own record
- non-genotyped with own record
- genotyped without own record
- non-genotyped without own record

Means of own GTa-reduc and means of parent average (PA) of GTa-full are compared.

Means are shown for each year from 2005 and forward for data where the mean is calculated on 10 individuals or more. First the results for chest width are shown, and then results for udder depth are shown lastly figures for stature are shown. Results are presented both as table and figures.

### **Chest width**

For chest width the mean GEBV is similar for own GTa-reduc and PA GTa-full for the four groups of cows.

Table7.9 Chest Width: mean GEBV (own reduc solution) and the parent average (PA) GEBV for cows, where parents are genotyped.

*Cows, which are genotyped and have own records.*

2018			9.7	7.3			6.9	7.3

### Udder depth

For udder depth the mean for own GTa-reduc and PA GTa-full are comparable for all four groups. However, the level of the GEBV differs between groups. Cows without records have higher breeding values than cows with record no matter if genotyped or not.

Table 7.14 Udder Depth: mean GEBV (own reduc solution) and the parent average (PA) GEBV for cows, where parents are genotyped.

*Cows, which are genotyped and have own records*

2013	674	100.8	100.5
2014	739	101.3	101.5
2015	321	101.7	102.3
2016	86	106.1	106.1
2017	52	111.8	110.9
2018			

Table 7. Stature: mean GEBV (own reduc solution) and the parent average (PA) GEBV for cows, where parents are genotyped.

*Cows, which are genotyped and have no records*

b_year	N	Own GTa_reduc	PA GTa-full
2014	475	104.6	104.7
2015	2109	104.4	103.9
2016	3222	103.0	102.8
2017	3451	104.5	104.1
2018	163	106.3	105.2

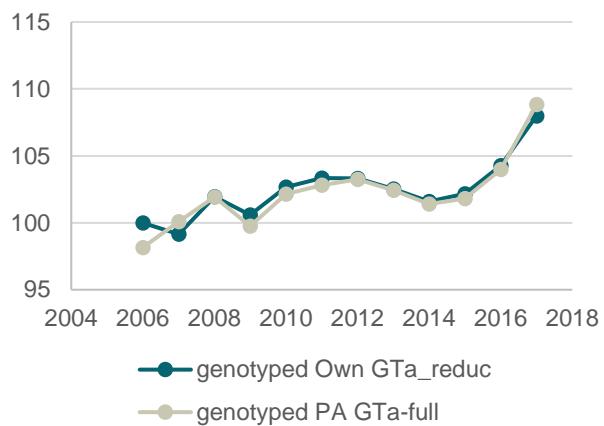

Table 7. Stature: mean GEBV (own reduc solution) and the parent average (PA) GEBV for cows, where parents are genotyped.

*Cows, which are non-genotyped and have no records*

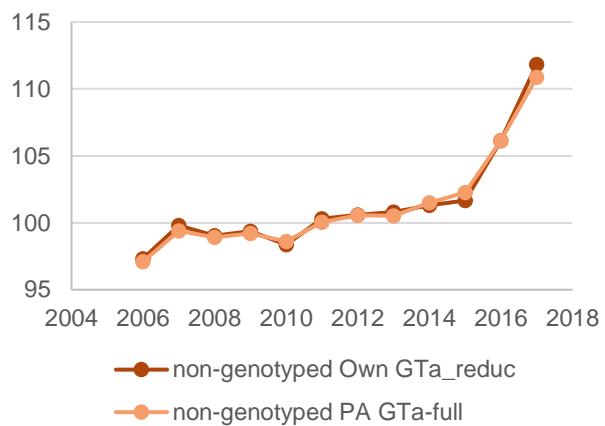

b_year	N	Own GTa_reduc	PA GTa-full
2014	211	100.8	100.6
2015	1003	102.5	102.3
2016	1411	102.6	102.3
2017	1043	104.2	103.9
2018	28	103.9	103.3

The mean GEBV for stature is increasing rapidly the last two years, which rises a minor concern. There is a high degree of similarity between own GTa-reduc and PA GTa-full.

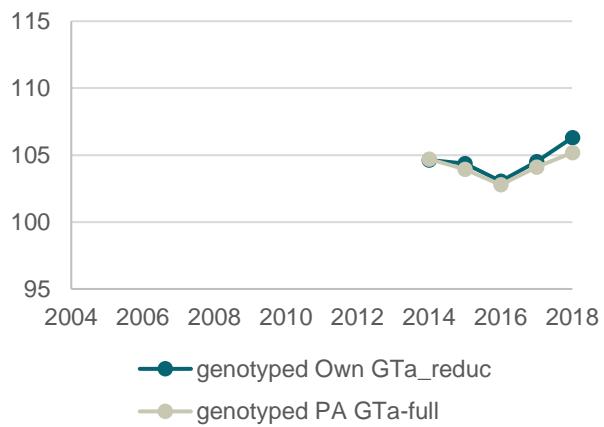

Stature: mean GEBV for own GTa-reduc and PA GTa-full for genotyped cows with own record

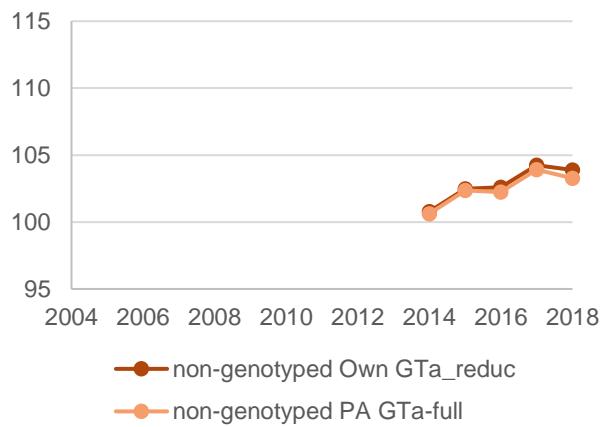

Stature: mean GEBV for own GTa-reduc and PA GTa-full for non-genotyped cows with own record

Stature: mean GEBV for own GTa-reduc and PA GTa-full for genotyped cows without own record

Stature: mean GEBV for own GTa-reduc and PA GTa-full for non-genotyped cows without own record

## 7. Comparison of PA GEBV and own GEBV for cows with records in full but not in reduc

These cows are having a record in full data but not in reduc data. Furthermore, only this includes only cows, where both parents are genotyped and have GEBV. Then parent average (PA) of GEBV full-GTa is calculated and compared with the cows own GEBV full-GTa and own GEBV reduc-GTa. Thus, the groups (full and reduc) of cows are equal size. Cows are divided into genotyped and non-genotyped cows

### Chest width:

Genotyped cows

	full_GTa	reduc_GTa	PA full_GTa	N
2014	101.1	101.9	101.4	475
2015	100.0	100.2	100.3	2109
2016	100.6	100.7	100.8	3222
2017	99.6	99.7	99.7	3451
2018	100.7	99.8	101.1	163

Non-genotyped cows

	full_GTa	reduc_GTa	PA full_GTa	N
2014	100.4	101.1	100.5	211

2016	100.9	100.9	100.9	1410
2017	100.0	100.3	100.0	1043
2018	99.3	98.4	99.1	28

### Udder depth:

Genotyped cows

	full_GTa	reduc_GTa	PA full_GTa	N
2014	102.6	102.5	102.0	475
2015	104.2	104.0	103.4	2109
2016	104.3	104.5	104.1	3222
2017	107.6	107.8	107.2	3451
2018	109.9	110.5	109.2	163

Non-genotyped cows

	full_GTa	reduc_GTa	PA full_GTa	N
2014	99.4	99.3	99.4	211
2015	102.3	102.0	102.2	1002
2016	102.5	103.0	102.6	1410
2017	105.7	106.3	105.7	1043
2018	110.1	110.3	109.7	28

### Stature:

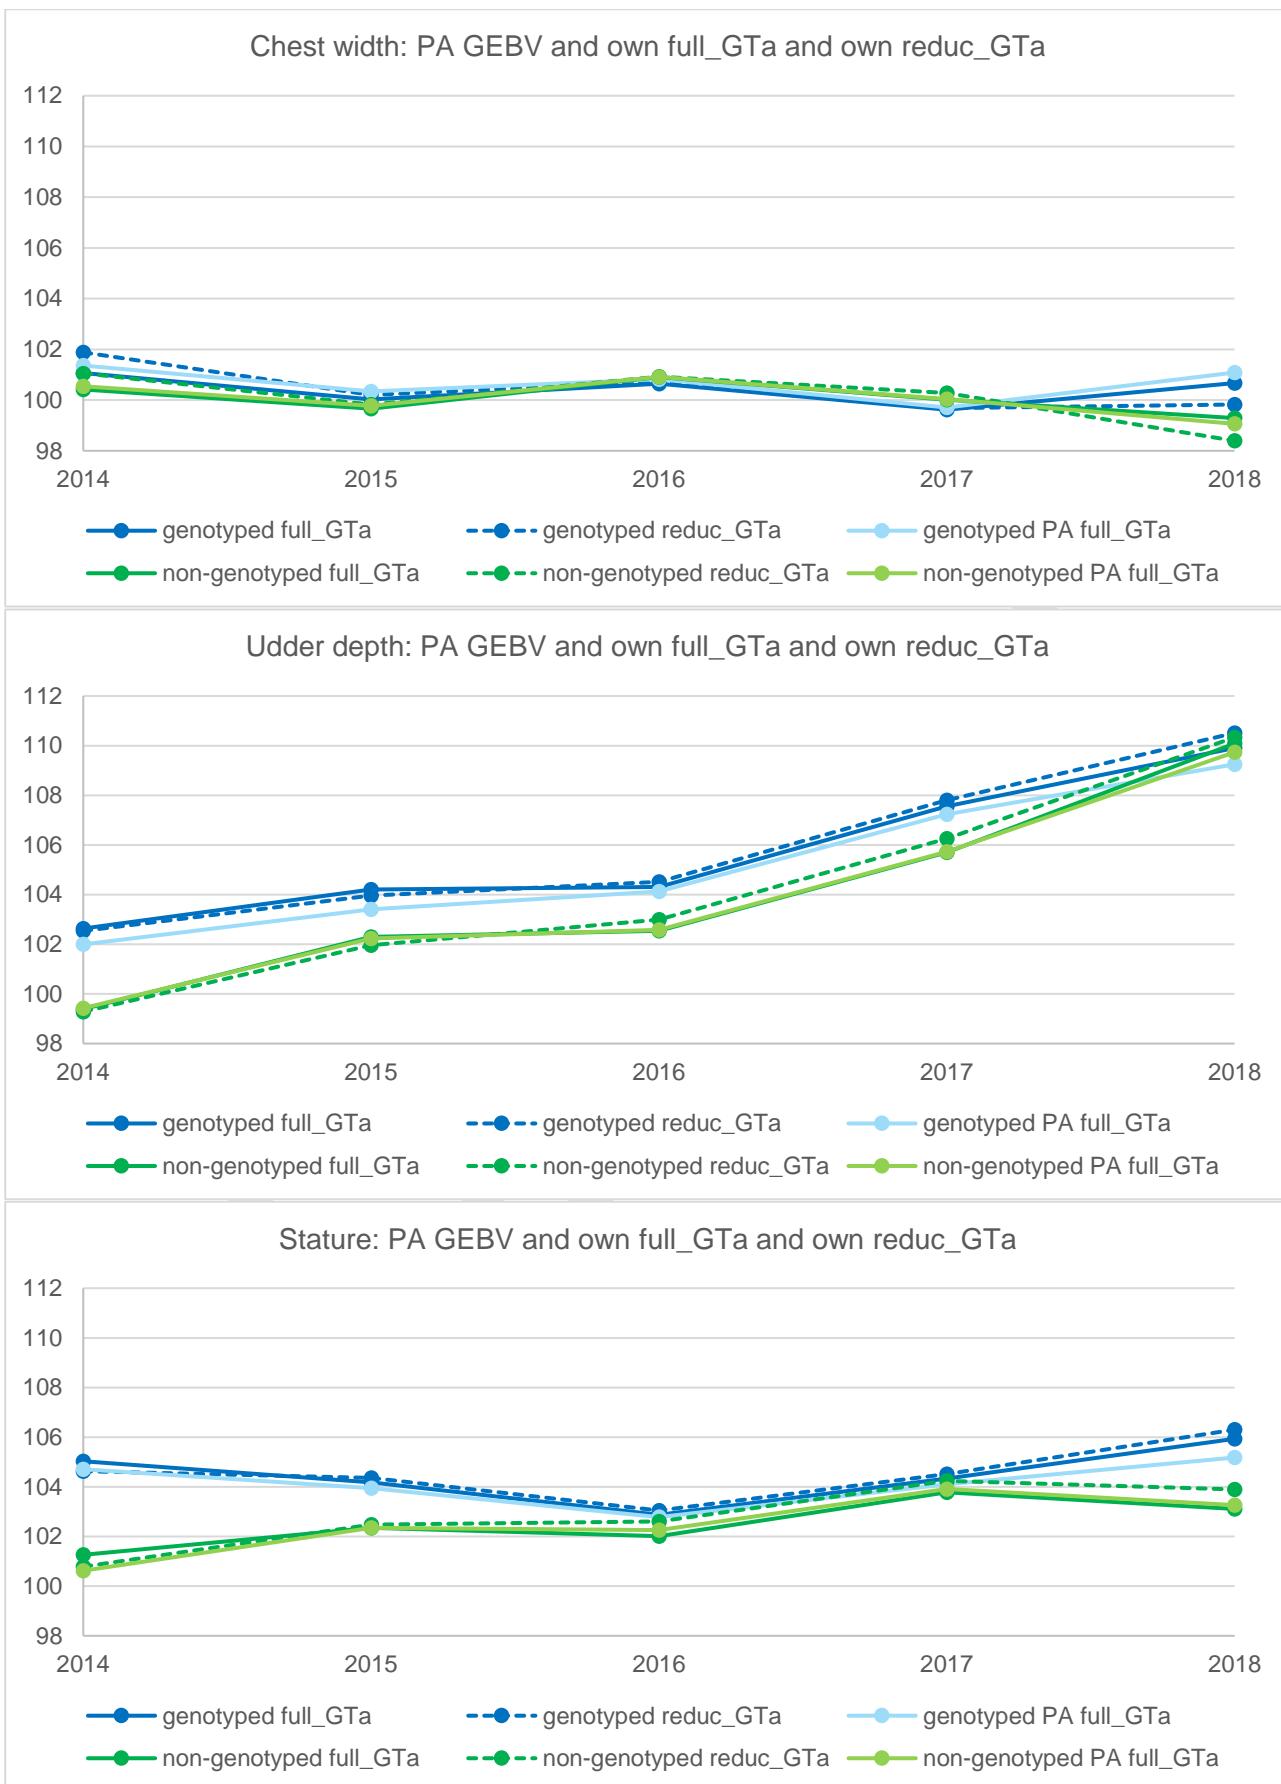

Genotyped cows

	full_GTa	reduc_GTa	PA full_GTa	N
2014	105.0	104.6	104.7	475
2015	104.2	104.4	103.9	2109
2016	102.9	103.0	102.8	3222
2017	104.3	104.5	104.1	3451
2018	105.9	106.3	105.2	163

Non-genotyped cows

	full_GTa	reduc_GTa	PA full_GTa	N
2014	101.3	100.8	100.6	211
2015	102.4	102.5	102.3	1002
2016	102.0	102.6	102.3	1410
2017	103.8	104.2	103.9	1043
2018	101.3	100.8	100.6	28

For these three traits there is a high similarity between own full-GTa, own reduc-GTa and Pa full-GTa.

## 8. Comparison of status1 bulls divided into four groups based on number of daughters with records in full data

For each bull with status 1, it is counted how many daughters he has, where the daughters have records in full data but no records in reduc dataset. Group1 is having most daughters while group5 is having fewest daughters.

	Group1	Group2	Group3	Group4	Group5
Number of daughters for the bull	[101; - ]	[71;100]	[46;70]	[10;45]	[ - ;9]
Number of bulls	181	86	88	32	34

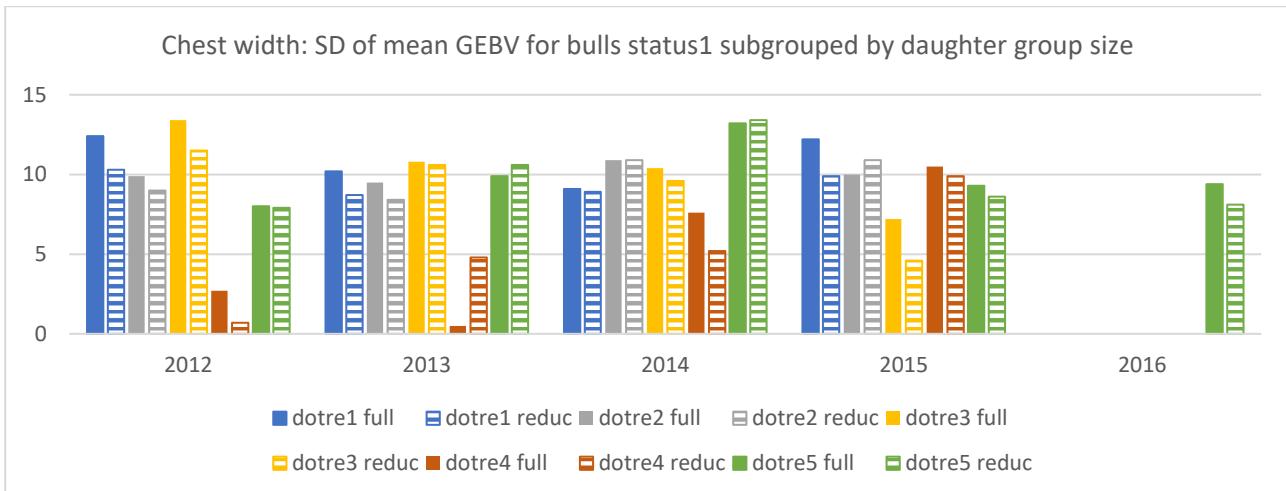

Chest width: mean GEBV for bulls status1 divided into 5 groups based on number of daughters with records in full data but no records in reduc data.

	1 full	1 reduc	2 full	2 reduc	3 full	3 reduc	4 full	4 reduc	5 full	5 reduc	N 1	N 2	N 3	N 4	N 5
2012	100.2	100.7	99.7	100.7	103.1	104.0	102.0	103.0	102.6	103.1	55	44	27	4	6
2013	99.9	100.8	104.0	104.2	100.6	100.9	103.6	105.0	95.0	96.7	42	26	32	2	3
2014	100.6	102.2	102.7	103.3	99.6	101.0	100.0	100.2	100.0	100.8	50	9	25	7	5
2015	101.6	100.1	103.4	103.8	93.5	93.3	94.0	94.5	98.2	101.1	34	7	4	18	8
2016							79.5	81.0	98.0	97.6				1	12
											181	86	88	32	34

Chest width: SD of mean GEBV for bulls status1 divided into 5 groups based on number of daughters with records in full data but no records in reduc data.

	1 full	1 reduc	2 full	2 reduc	3 full	3 reduc	4 full	4 reduc	5 full	5 reduc	N 1	N 2	N 3	N 4	N 5
2012	12.4	10.3	9.9	9.0	13.4	11.5	2.7	0.7	8.0	7.9	55	44	27	4	6
2013	10.2	8.7	9.5	8.4	10.8	10.6	0.5	4.8	9.9	10.6	42	26	32	2	3
2014	9.1	8.9	10.9	10.9	10.4	9.6	7.6	5.2	13.2	13.4	50	9	25	7	5
2015	12.2	9.9	10.0	10.9	7.2	4.6	10.5	9.9	9.3	8.6	34	7	4	18	8
2016									9.4	8.1				1	12
											181	86	88	32	34

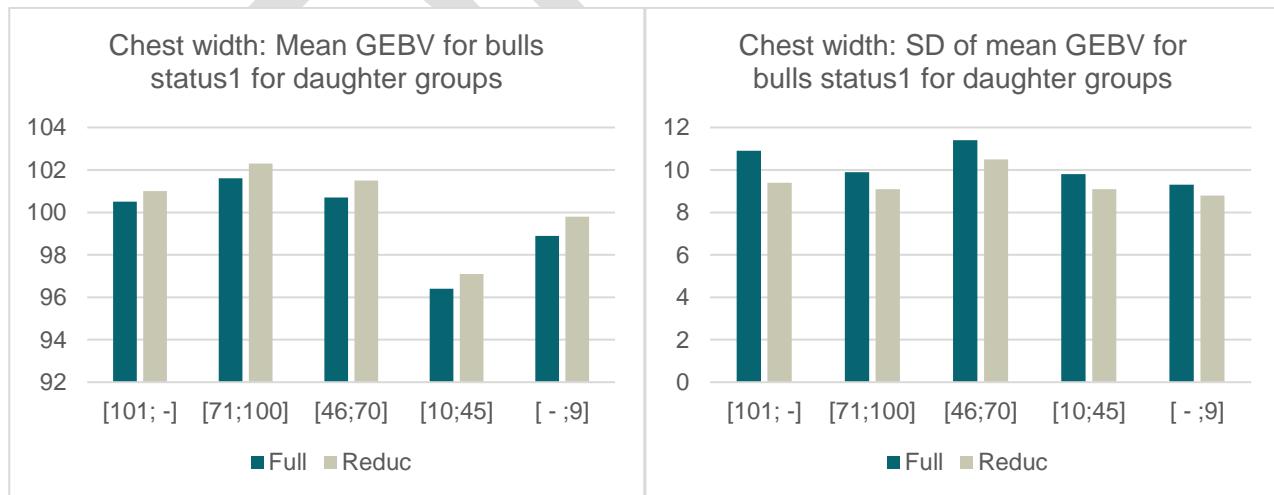

Since there is almost no genetic trend for chest width in this time period, it is reasonable to compare groups without looking at birth year for the bulls. This is advantageously, because of the low number of bulls in each group year.

The mean GEBV-full is lower than mean GEBV-reduc for the five groups, while the SD of the mean GEBV is higher for full than for reduc.

Group	N daughters	N bulls	Mean GEBV		SD of mean GEBV		
			Full	Reduc	Full	Reduc	diff
1	[101; -]	181	100.5	101.0	10.9	9.4	1.5
2	[71;100]	86	101.6	102.3	9.9	9.1	0.8
3	[46;70]	88	100.7	101.5	11.4	10.5	0.9
4	[10;45]	32	96.4	97.1	9.8	9.1	0.7
5	[ - ;9]	34	98.9	99.8	9.3	8.8	0.5

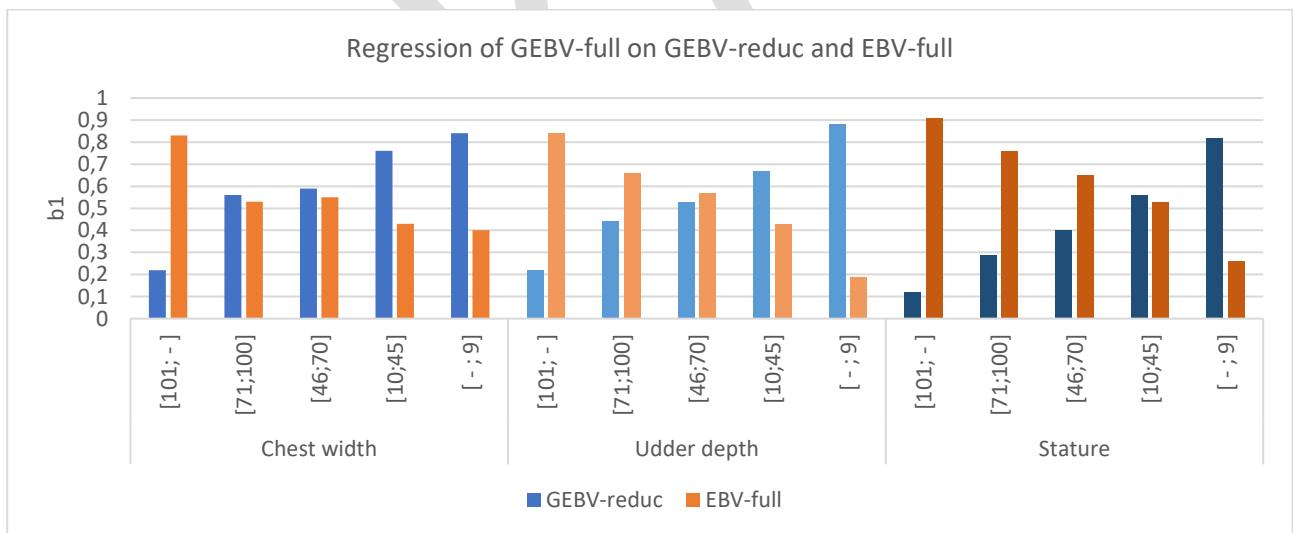

## 9. Regression of GEBV\_full on GEBV\_reduc and Trad\_full for status1 bulls divided into daughter groups

For bulls status1 divided into groups based on number of daughters with records in full but not in reduc data. Traditional breeding values EBV's for chest width and udder depth are from a model with all animals (also international bulls) but stature is from a model without international bulls. This should have no effect since international bulls should not affect the breeding value.

b1 values for GEBV-reduc is low in group1 (many daughters) and high in group4 (few daughters) and b1 values for EBV-full is highest for group1 and lower for group4 for chest width, udder depth and stature. Thus, as expected, bulls with many daughters are less depending on genomic value and more depending on phenotypes from daughters, while for bulls with few daughters, the genotype is more important than the phenotypes from the daughters.

b1 values for GEBV-reduc and EBV-full in a regression model for GEBV-full for bulls status1 with daughters with own record in full data but not in reduc data. Bulls are divided into groups based on number of daughters.

		Group 1	Group 2	Group 3	Group 4	Group 5
	N daughters/bull Number of bulls	[101; - ] 181	[71;100] 86	[46;70] 88	[10;45] 32	[ - ; 9] 34
Chest width	GEBV_reduc	0.22	0.56	0.59	0.76	0.84
	Trad_full	0.83	0.53	0.55	0.43	0.40
	R-Square	0.99	0.98	0.97	0.94	0.93
Udder depth	GEBV_reduc	0.22	0.44	0.53	0.67	0.88
	Trad_full	0.84	0.66	0.57	0.43	0.19
	R-Square	0.99	0.99	0.98	0.97	0.96
Stature	GEBV_reduc	0.12	0.29	0.40	0.56	0.82
	Trad_full	0.91	0.76	0.65	0.53	0.26
	R-Square	0.99	0.99	0.99	0.97	0.96

## 10. Comparison of own GEBV and parent average GEBV where cows are divided into four groups by PA GEBV.

Those cows are cows where parents are genotyped. Furthermore, cows are having records in full data but not in reduc. And based on PA GEBV cows are (by birth year) divided into four groups of PA, where PA1 are cows with the highest PA GEBV, and PA4 are cows with the lowest PA GEBV. Therefore, by birth year the number of cows in each PA group is similar. Thereafter the cows are divided into genotyped and non-genotyped cows. The aim is to check if different level of PA affects the trend for GEBV. Those results are for stature only.

Number of cows in each group by birth year

	PA1	PA2	PA3	PA4
2014	171	171	172	172
2015	777	779	778	777
2016	1158	1158	1158	1158
2017	1123	1124	1124	1123
2018	48	48	48	47

Stature: Genotyped cows with own record in full, but without own record in reduc.

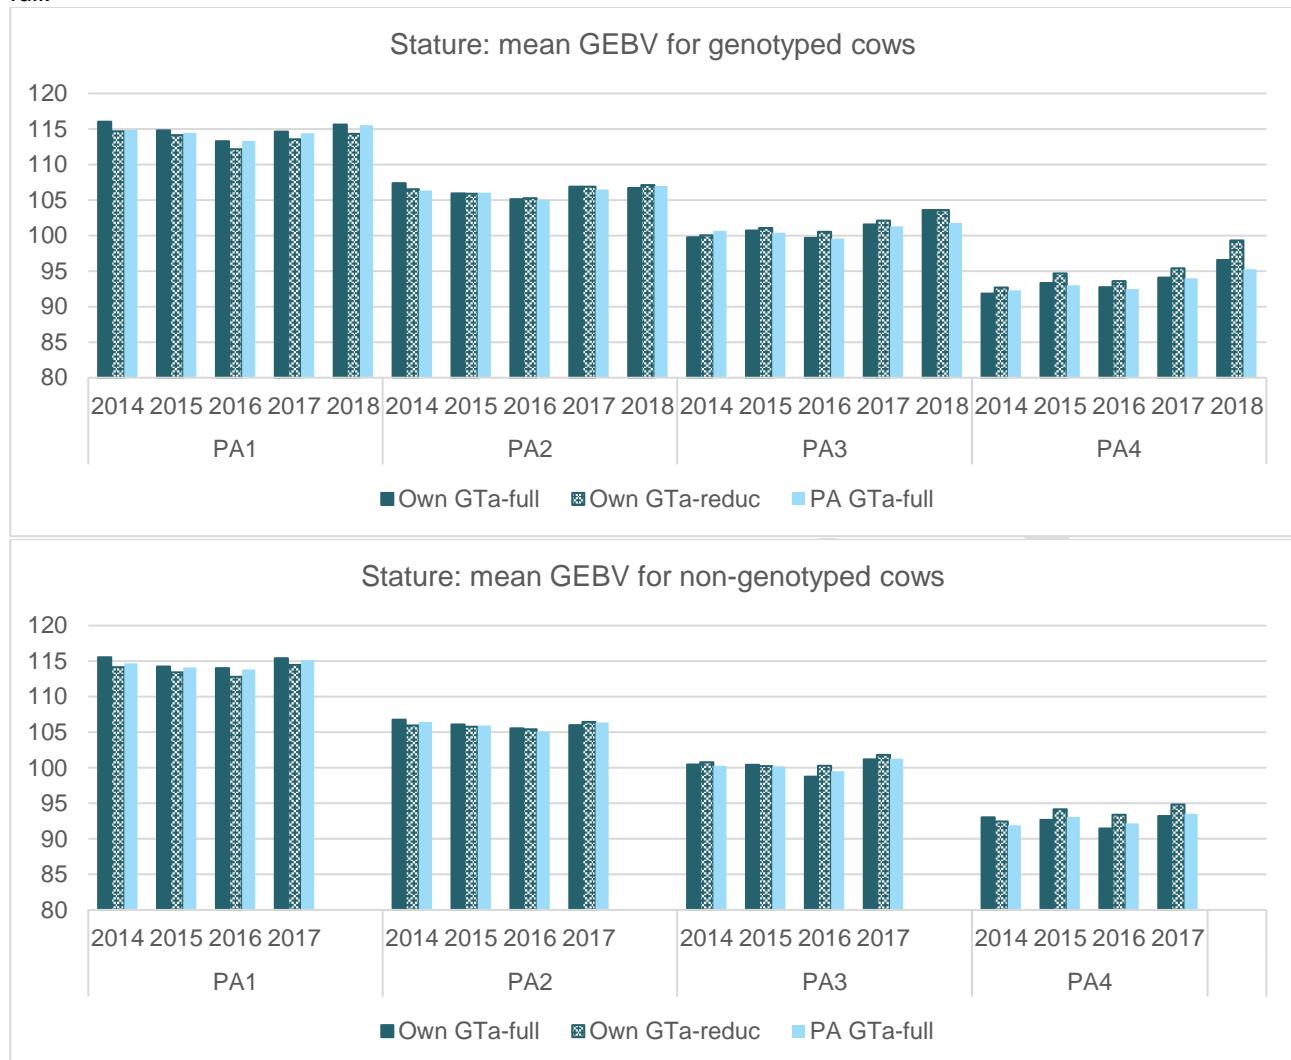

group	b-year	Own GTa-full	Own GTa-reduc	PA GTa-full	N
PA1	2014	116.0	114.7	114.9	140
	2015	114.8	114.1	114.4	570
	2016	113.3	112.2	113.3	818

	2015	92.6	94.2	93.1	282
	2016	91.5	93.4	92.2	388
	2017	93.2	94.9	93.5	257
	2018	95.5	96.1	94.7	11

No matter the PA group there is a positive trend for stature for the period 2014 until 2018.

Overall there is a great similarity of level of own GEBV GTa-full, own GEBV GTa-reduc and PA GEBV GTa-full.

## 11. GTa-reduc2 for 2017, 2018, 2019 and 2020 for bulls

For bulls status1 GEBV for GTa-full and GTa-reduc2 and GTa-reduc2 for years 2017 to 2020. This means that each year more data are available.

For chest width, udder depth and stature the full, reduc2, reduc2\_2017, reduc2\_2018, reduc2\_2019 and reduc2\_2020 are showing similar levels inside each birth year for bulls with status1. For the later years the twostep value is lower than the singlestep values.

### Chest width:

2018	2043	0	0	0	0	1147
2019	0	0	0	0	0	0
2020	0	0	0	0	0	0

Mean GEBV and SD of mean GEBV for cows with records in 2019 but not in 2018 where cows are divided into genotyped and non-genotyped cows.

Overall there is high similarity of mean GEBV for reduc2\_18 and reduc2\_19 for both genotyped and non-genotyped cows for each trait.

However, it is a minor concern that the SD for reduc2\_18 and reduc2\_19 is similar for genotyped cows. It was expected that the SD for reduc2\_19 should be higher than for reduc2\_18, since accuracy is increased. This is not a concern for non-genotyped cows, where SD for reduc2\_19 is higher than reduc2\_18.

### Chest width:

Chest width: mean GEBV and SD of mean GEBV for genotyped cows for 2018 and 2019.

b-year	N	Mean GEBV		SD of mean GEBV	
		reduc2_18	reduc2_19	reduc2_18	reduc2_19
2014	2	99.3	99.4	1.0	1.3
2015	1093	101.6	101.7	9.8	9.9
2016	9249	101.4	101.7	9.6	9.9
2017	330	101.7	101.8	10.0	10.1

Chest width: mean GEBV and SD of mean GEBV for non-genotyped cows for 2018 and 2019.

b-year	N	Mean GEBV		SD of mean GEBV	
		reduc2_18	reduc2_19	reduc2_18	reduc2_19
2014	30	102.1	101.0	7.7	8.8
2015	9803	101.3	101.2	6.2	7.1
2016	54384	101.6	101.8	6.1	7.2
2017	1394	101.5	101.5	5.6	6.7

### Udder depth:

Udder depth: mean GEBV and SD of mean GEBV for genotyped cows for 2018 and 2019.

b-year	N	Mean GEBV		SD of mean GEBV	
		reduc2_18	reduc2_19	reduc2_18	reduc2_19
2014	2	110.9	111.4	11.7	15.6
2015	1093	102.8	102.8	10.6	10.6
2016	9249	102.7	102.4	10.0	10.2
2017	330	104.7	104.3	10.4	10.6

Udder depth: mean GEBV and SD of mean GEBV for non-genotyped cows for 2018 and 2019.

b-year	N	Mean GEBV		SD of mean GEBV	
		reduc2_18	reduc2_19	reduc2_18	reduc2_19
2014	30	95.1	94.9	6.4	6.3

2015	9803	99.7	99.8	6.8	8.4
2016	54384	100.7	100.5	6.6	8.3
2017	1394	102.8	102.4	6.9	8.3

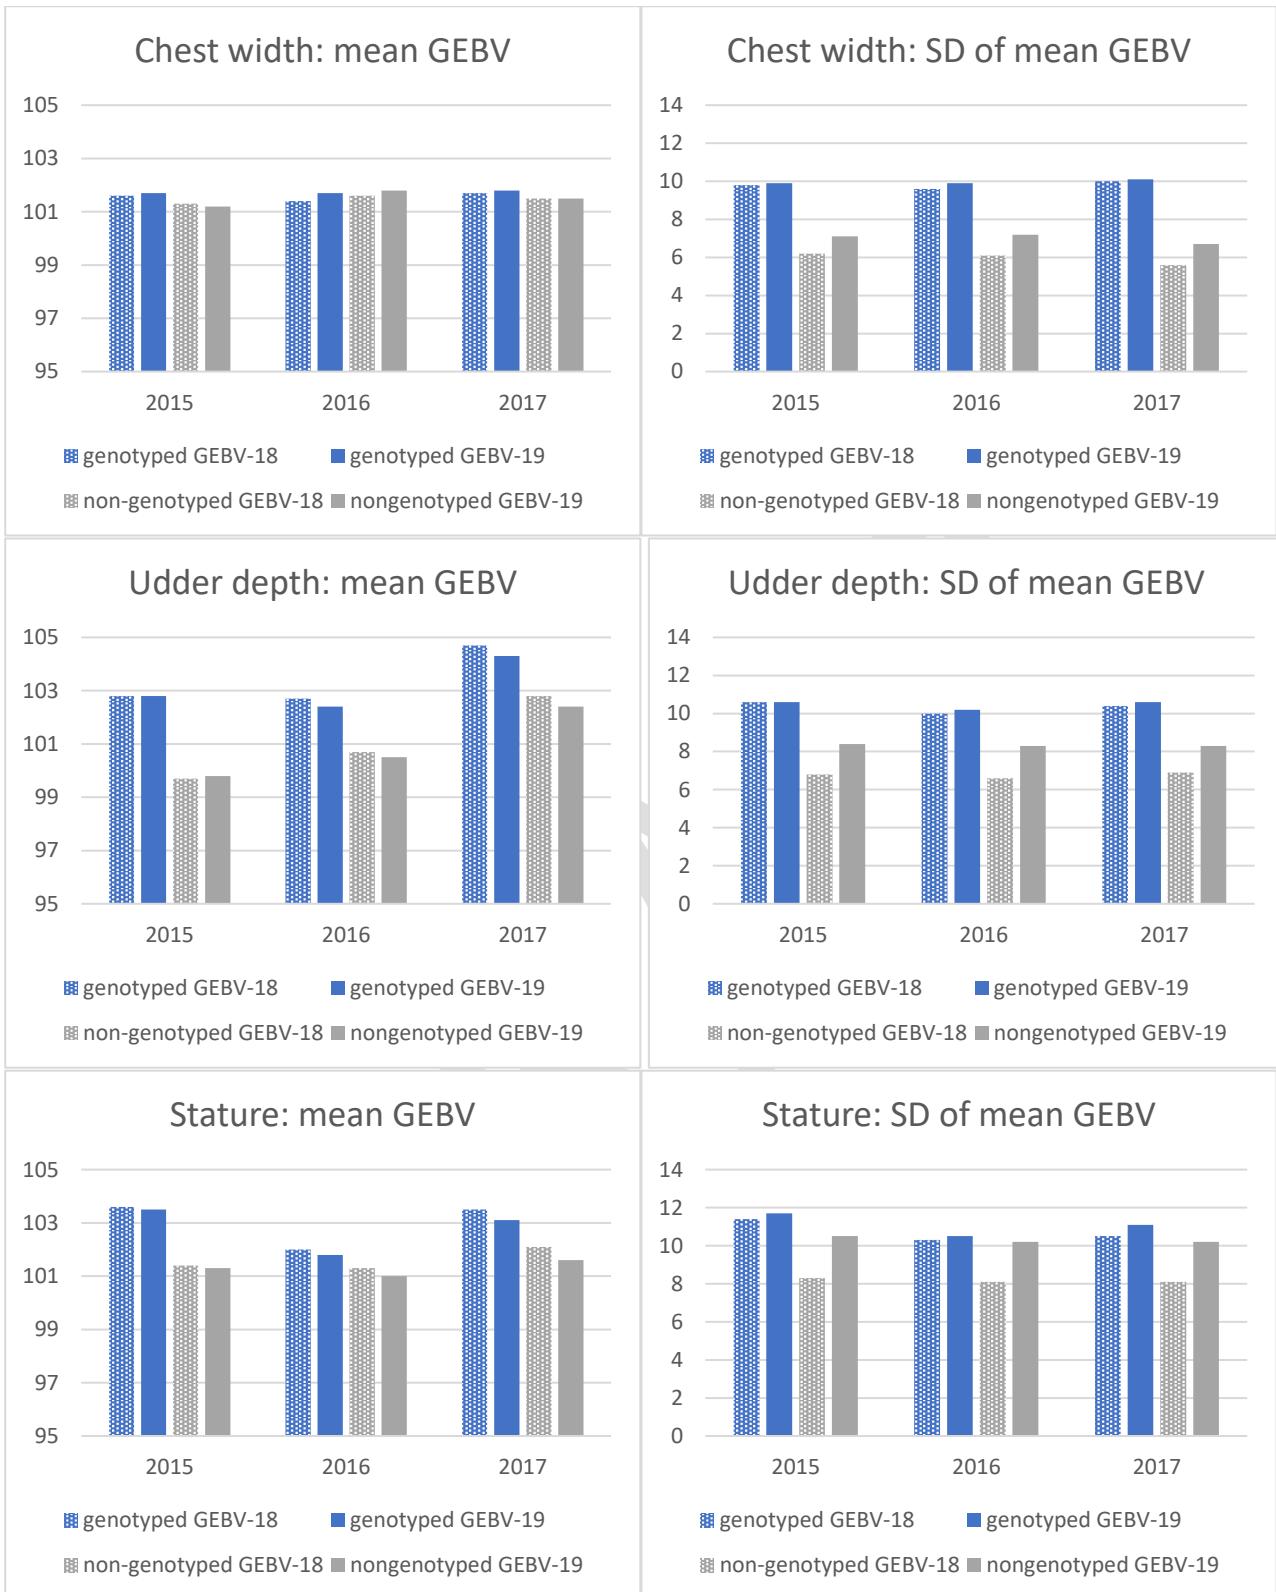

### Stature:

Stature: mean GEBV and SD of mean GEBV for genotyped cows for 2018 and 2019.

b-year	N	Mean GEBV		SD of mean GEBV	
		reduc2_18	reduc2_19	reduc2_18	reduc2_19
2014	2	119.5	118.9	8.6	8.3
2015	1093	103.6	103.5	11.4	11.7
2016	9249	102.0	101.8	10.3	10.5
2017	330	103.5	103.1	10.5	11.1

Stature: mean GEBV and SD of mean GEBV for non-genotyped cows for 2018 and 2019.

b-year	N	Mean GEBV		SD of mean GEBV	
		reduc2_18	reduc2_19	reduc2_18	reduc2_19
2014	30	96.4	99.6	6.8	10.1
2015	9803	101.4	101.3	8.3	10.5
2016	54384	101.3	101.0	8.1	10.2
2017	1394	102.1	101.6	8.1	10.2

Correlation between GTa-reduc2\_18 and GTa-reduc2\_19 for cows with record in 2019 but not in 2018.  
Divided into birth year and genotyped /non-genotyped.

b-year	Chest width		Udder depth		Stature	
	genotyped	non-genotyped	genotyped	non-genotyped	genotyped	non-genotyped
2014		0.64		0.93		0.57
2015	0.98	0.78	0.99	0.86	0.98	0.80
2016	0.97	0.77	0.97	0.84	0.97	0.80
2017	0.96	0.79	0.97	0.81	0.97	0.79

Number of cows in each interval of diff where diff=GTa-reduc2\_19- GTa\_reduc2\_18.

diff	Chest width		Udder depth		Stature	
	genotyped	non-genotyped	genotyped	non-genotyped	genotyped	non-genotyped

sum	10674	65611	10674	65611	10674	65611

### 13. Interbull validation for GTa (and two-step) for udder depth

For interbull validation the data contains Nordic Holstein bulls born after 2011 and minimum of 25 daughters in the GTa-full model and no daughters in reduc dataset. The dataset contains 489 bulls.

Deregressed proof is set for each bull.

Based on the sire and the maternal grandsire the pedigree index is set.

Furthermore, the interbull validation for two-step model is mentioned for comparison.

Regression 1: deregressed proof on GTa-reduc

Regression 2: deregressed proof on pedigree index

Based on a regression model the R-square and the parameter estimate (b1) is solved.

The R-square is higher for GTa-reduc than for pedigree index, and the slope is closer to 1 for GTa-reduc than for pedigree index.

Thus, the GTa-reduc better fits the value for deregressed proof than the pedigree index does.

	R-square	Parameter estimate
Single-step		
Deregressed proof on GTa-reduc	0.67	0.84
Deregressed proof on pedigree index	0.15	0.73
Two-step		
Deregressed proof on GEBV-reduc	0.65	0.86
Deregressed proof on pedigree index	0.14	0.72

## 14. Legarra Reverter regression for GTa (and two-step) for udder depth

The Legarra Reverter regression examines how well the GTa-full and GTa-reduc/GTa-reduc2 are fitted. The Legarra Reverter regression is based on the same dataset as used in the interbull validation.

Regression 1: GTa-full on GTa-reduc

Regression 2: GTa-full on GTa-reduc2

Based on a regression model the R-square and the parameter estimate (b1) is solved.

The R-square is nearly similar for GTa-reduc and GTa-reduc2.

The b1 values are high for both GTa-reduc and GTa-reduc2, and close to 1.

	R-square	Parameter estimate
Single-step		
GTA-full on GTa-reduc	0.84	0.95
GTA-full on GTa-reduc2	0.83	0.93
Two-step		
GEBV-full on GEBV-reduc	0.82	0.91

## 15. Interbull validation for status1 bulls sub-grouped by number of daughters

Bulls from the interbull validation mentioned earlier is sub-grouped by the number of daughters, as earlier described as dotre\_groups.

Udder depth:

	Group 1	Group 2	Group 3	Group 4	Group 5
N daughters/bull	[101; - ]	[71;100]	[46;70]	[10;45]	[ - ; 9]
Number of bulls	172	85	87	20	0
Deregressed proof on GTa-reduc	0.83	0.86	0.90	1.10	-
R-Square	0.71	0.66	0.58	0.78	-
Deregressed proof on pedigree index	0.89	0.50	0.62	0.70	-
R-Square	0.22	0.07	0.11	0.11	-

## 16. Legarra Reverter regression for status1 bulls sub-grouped by number of daughters.

Same bulls as in Interbull validation above.

There seems to be some disturbances in group3 as it does not fit the tendency either for b1 or for R-square. So far there is no explanation for this.

Udder depth:

	Group 1	Group 2	Group 3	Group 4	Group 5
N daughters/bull	[101; - ]	[71;100]	[46;70]	[10;45]	[ - ; 9]
Number of bulls	172	85	87	20	0
GTa-full on GTa-reduc	0.95	0.97	0.86	1.06	-
R-Square	0.82	0.86	0.66	0.92	-
